What are Bayesian Networks?

Definition and Overview

Bayesian networks, also known as belief networks or probabilistic graphical models, are graphical representations of probabilistic relationships among a set of variables. They encode conditional dependencies through directed acyclic graphs (DAGs), enabling efficient computation of joint probability distributions. These models are grounded in Bayes' theorem, which updates the probability estimates as new evidence becomes available.

Core Components of Bayesian Networks

Key Properties

- Conditional Independence: The structure of the network encodes which variables are conditionally independent, reducing the complexity of probability calculations.
- Factorization: The joint distribution over all variables can be factorized into the product of local conditional distributions, simplifying inference.

Understanding Bayesian Networks

Definition and Fundamental Concepts

A Bayesian network (also known as a belief network or probabilistic directed acyclic graph) is a graphical model that encodes probabilistic relationships among a set of variables. It uses nodes to represent variables and directed edges to signify conditional dependencies.

Key features include:

- Directed Acyclic Graph (DAG): The structure contains no cycles, ensuring a clear causal or dependency directionality.
- Conditional Probability Distributions (CPDs): Each node has an associated CPD that quantifies the probability of the variable given its parents.
- Joint Probability Representation: The entire joint distribution over all variables can be factorized based on the network structure.

Mathematically, for a set of variables $\{X_1, X_2, \dots, X_n\}$, the joint probability can be expressed as:

$$P(X_1, X_2, \dots, X_n) = \prod_{i=1}^n P(X_i \mid \text{Parents}(X_i))$$

This factorization simplifies complex joint distributions into manageable local distributions.

Structural Components of Bayesian Networks

- Nodes: Each node corresponds to a random variable, which could be discrete or continuous.
- Edges: Directed edges imply direct probabilistic influence; for example, an edge from X to Y suggests X influences Y .
- Conditional Probability Tables (CPTs): For discrete variables, CPTs specify the probability of each state conditioned on parent variables.
- Markov Assumption: Each variable is conditionally independent of its non-descendants given its parents.

Constructing a Bayesian Network

Building a Bayesian network involves:

- Domain Knowledge Acquisition: Understanding the causal or correlational relationships among variables.
